

RADIO SKY NEWS

2024 NOVEMBER.

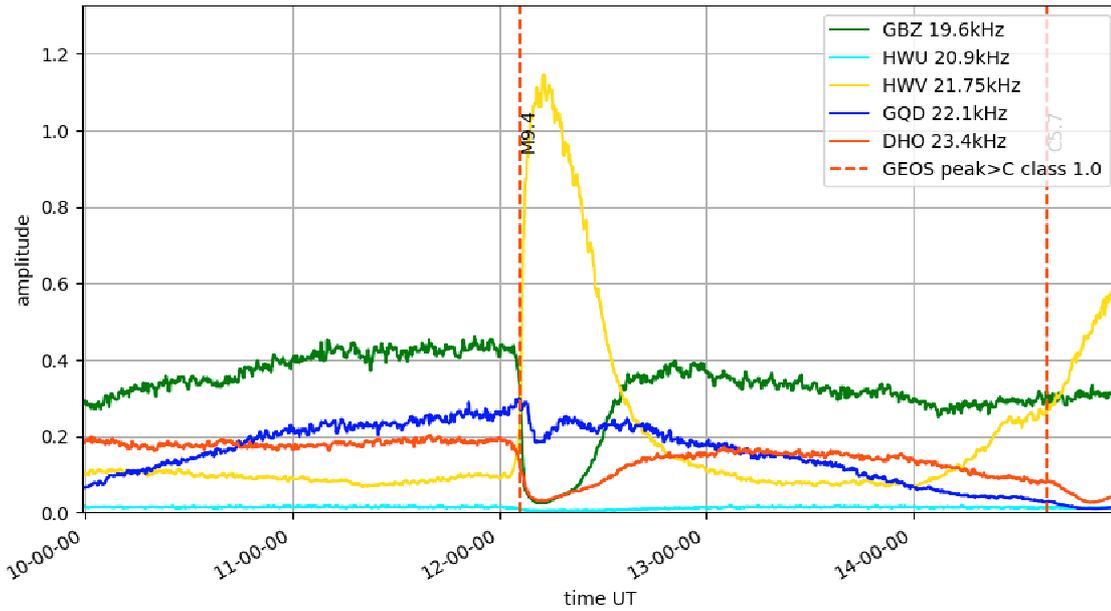

VLF SID OBSERVATIONS.

Solar flare activity has been slowly decreasing over the last three months, a total of 83 classified flares being recorded as SIDs in November. In October there were 91. The strength of the flares has however increased slightly, with 51% C-class and 48% M-class. In October it was 66% C-class and 33% M-class. We did only record a single X-flare, compared with three in October. Some of our signals have been very disturbed due to the low solar altitude, so this has perhaps biased our detection ability to the stronger events. There are also plenty of flares that have overlapped to produce double peaked SIDs on some signals, and single SIDs on other signals.

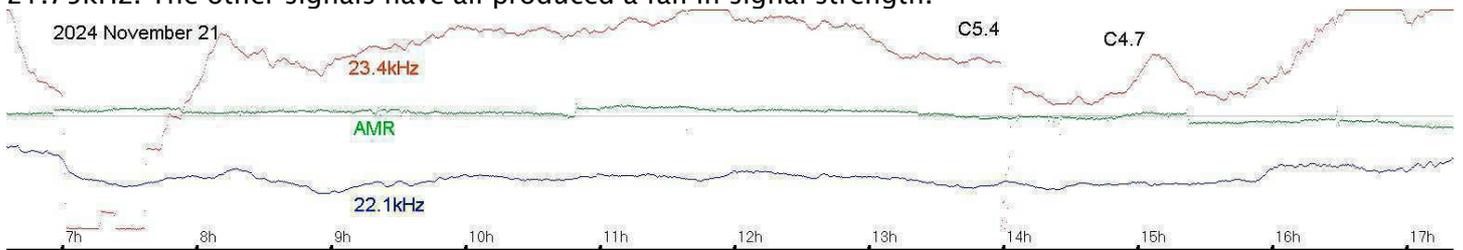

This recording by Colin Clements shows the M9.4 flare peaking just after midday on the 10th. Just shy of X-category, these three signals very clearly show the different SID shapes. 21.75kHz (blue) has a rising signal, while 37.5kHz (black) is inverted. 23.4kHz (red) has a 'spike and wave' shape, its true peak clearly aligned with the other two shapes.

SIDs vlf profile for 2024-11-10

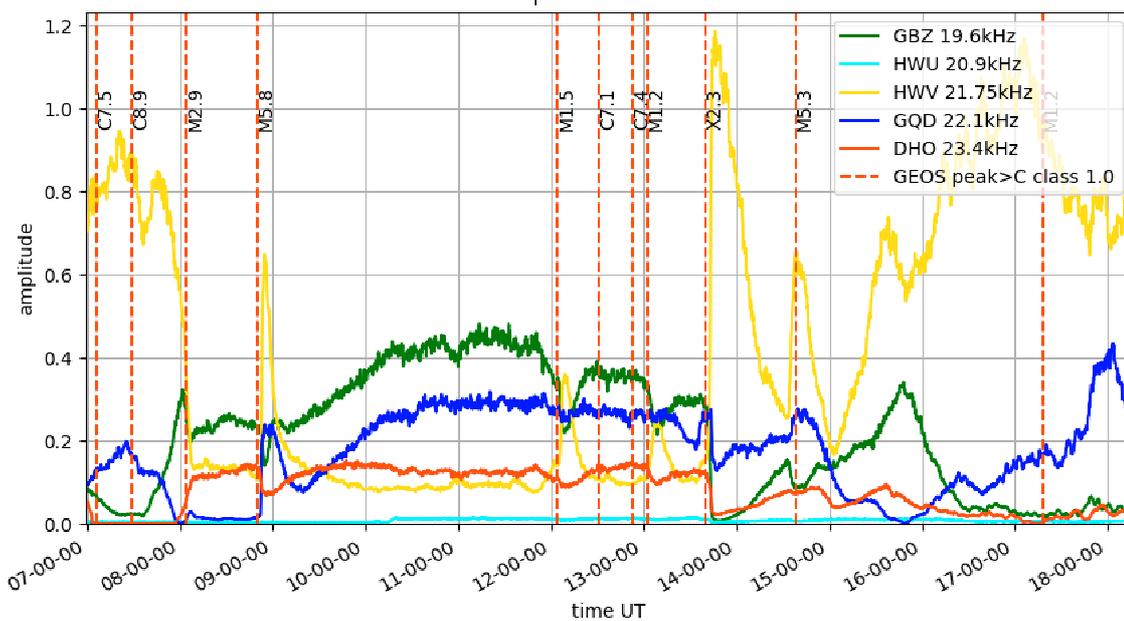

This recording by Mark Prescott includes some more signals, a very strong response recorded at 21.75kHz. The other signals have all produced a fall in signal strength.

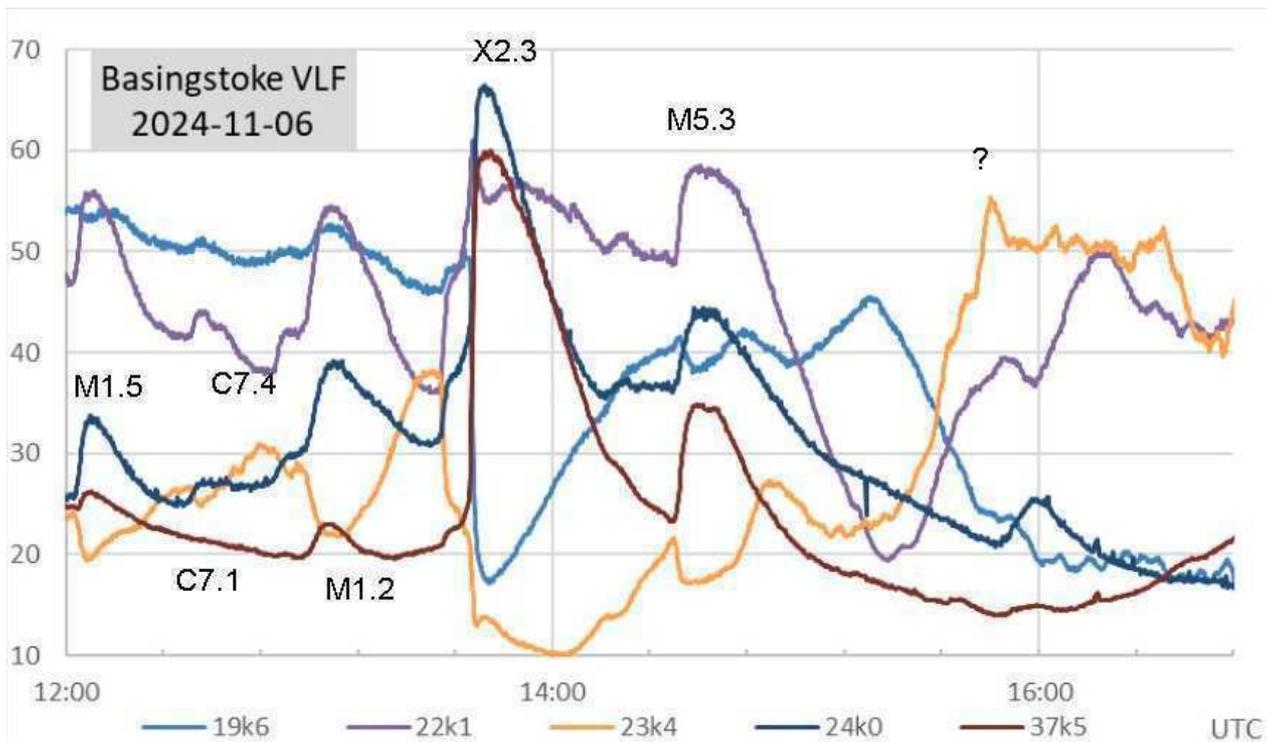

Not all days were as clear as the 10th. My recording shows the 21st, with a very noisy 23.4kHz. The two C-class flares have been completely hidden by the general ionospheric instability. I have marked their rough positions. It also shows the very early sunset, starting around 15:30UT.

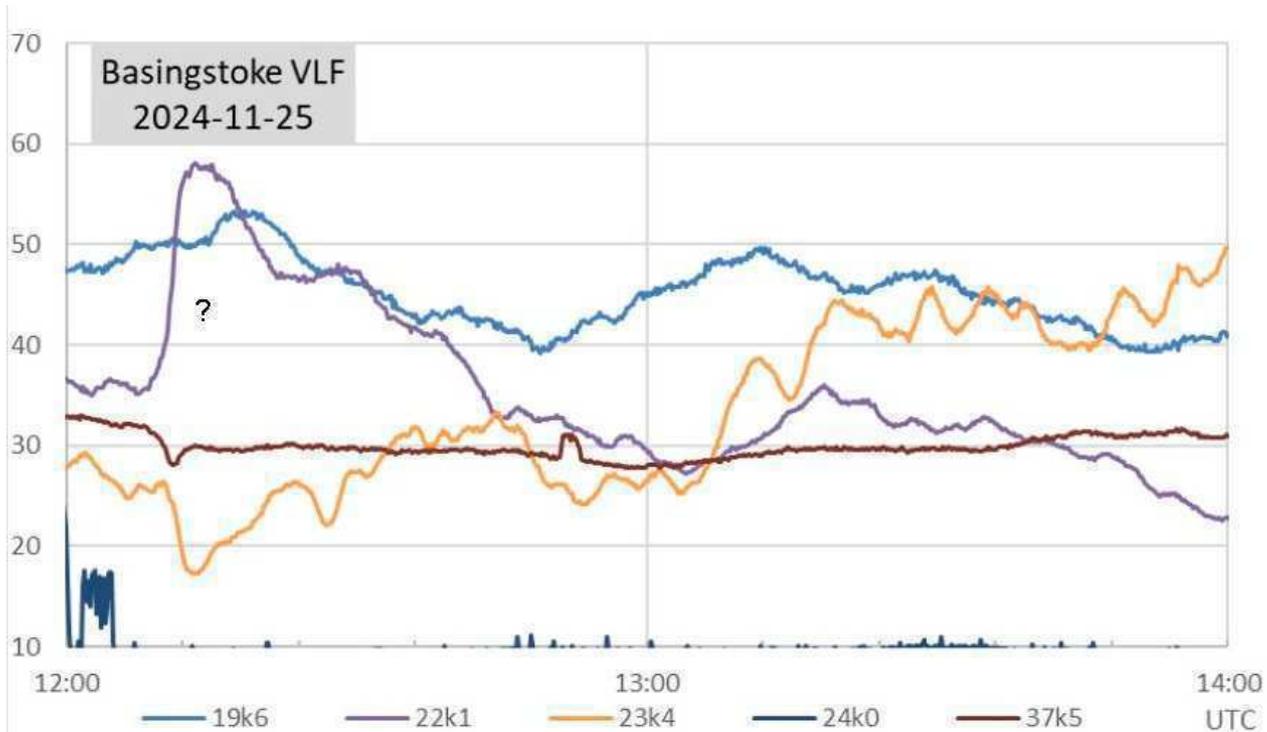

SIDs vlf profile for 2024-11-06

The 6th was the busiest day in November, including the X2.3, shown in Mark Prescott's recording. The strongest of the flares are clearly recorded as SIDs, but the strong C7.1 and C7.4 flares are well hidden.

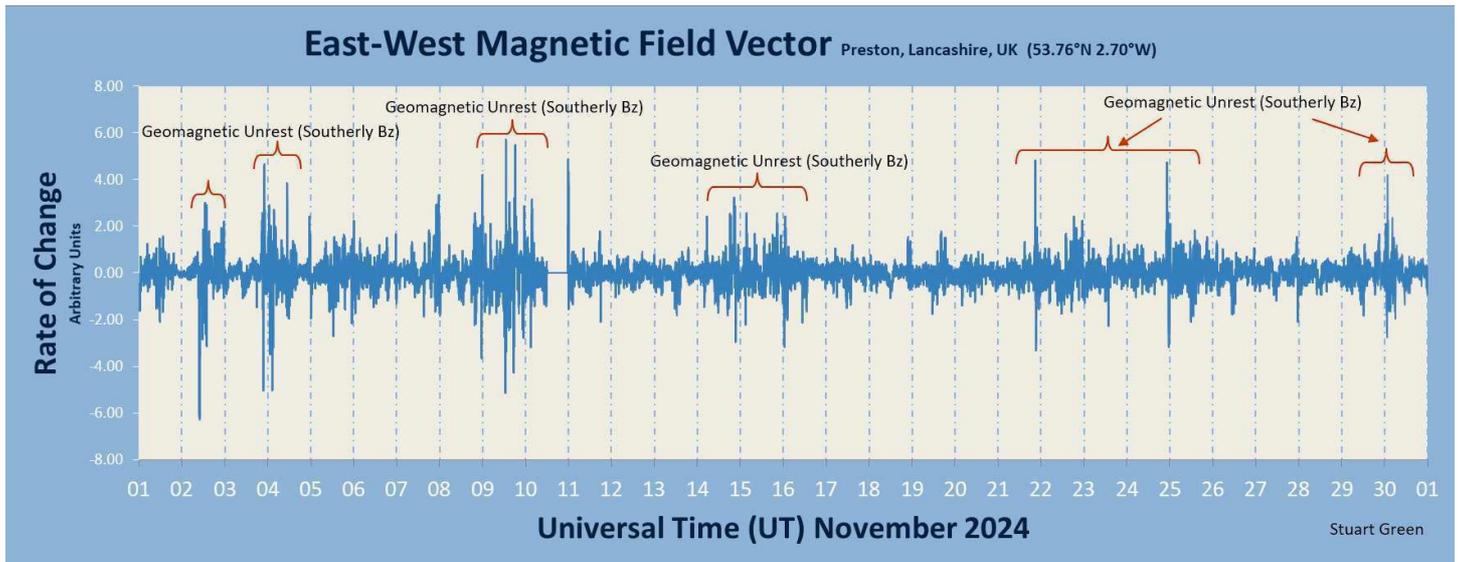

Paul Hyde's recording shows just the afternoon period, but again shows a very weak response to the C7.1 and C7.4 flares. The X2.3 flare is interesting as all of the signals appear to have a double-peaked SID, an effect not seen in other recordings. The 'spike and wave' SID at 23.4kHz has a very strange shape, tricky to analyse without guidance from the other signals. This was the only X-flare in the GOES satellite data for November, so we were lucky that it was so well timed.

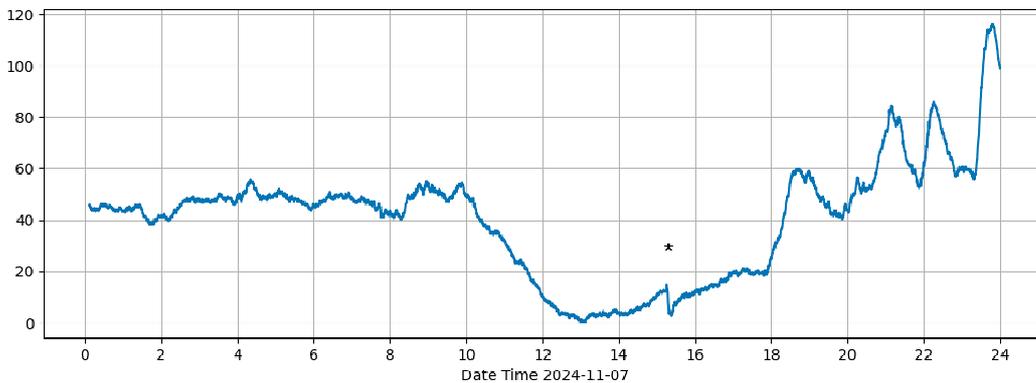

Activity decreased towards the end of the month, Paul Hyde's recording from the 25th showing just a single unclassified SID during the afternoon. This event was recorded by nine observers, and so is not local interference. There was an M9.4 flare early in the morning followed by a C5.4 flare at 10:48UT, but they were not widely recorded.

MAGNETIC OBSERVATIONS.

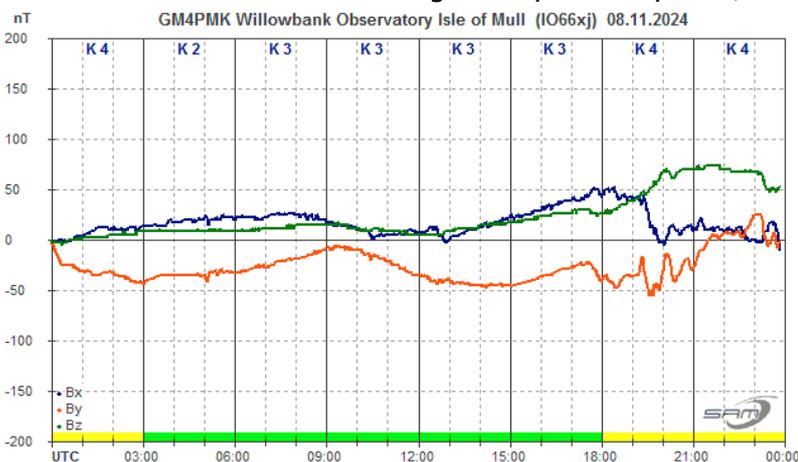

Stuart Green's summary of the month's activity shows some disturbance through most of the period. The Bartels chart also shows long periods of disturbance. Most of the activity was fairly mild, and appears to be from the solar wind rather than CMEs. We did record one potential CME impact, shown in Callum Potter's chart from the 7th:

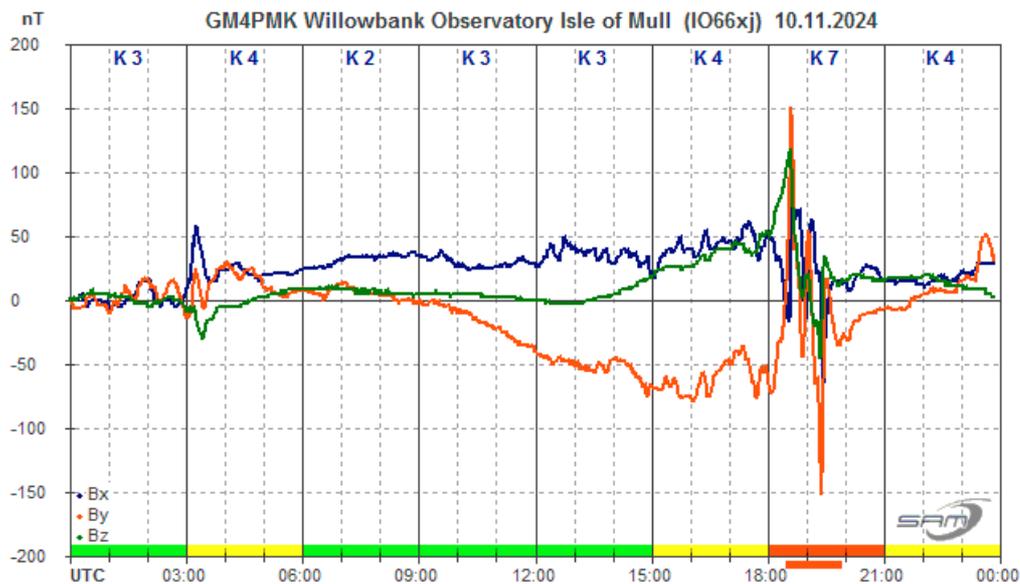

Wasbister Magnetometer (59.17N,3.06W)

The impact is at about 15:15UT, marked '*'. The STCE bulletin suggests that a CME from the 4th was the cause. There were lots of strong flares early in the month, some with CMEs directed away from Earth, so the exact source is not known. The resulting activity was very mild, shown in Roger Blackwell's recording from the 8th:

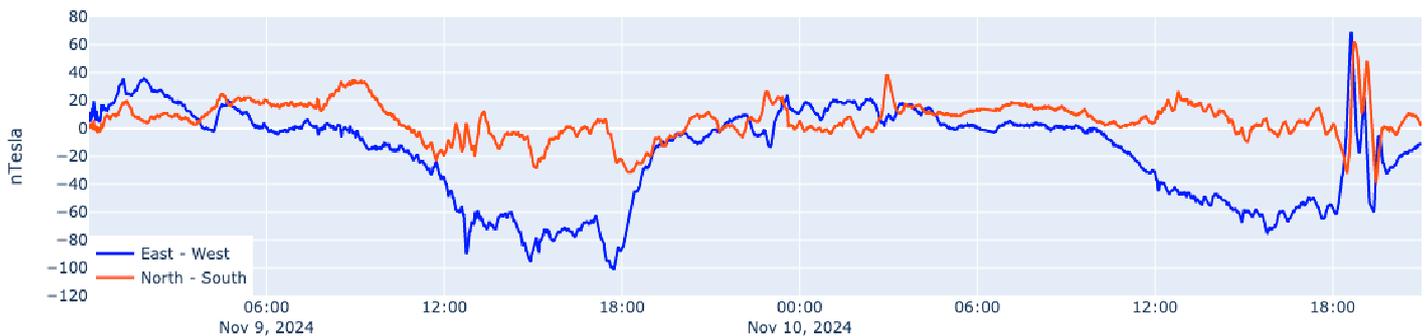

The most active period was the evening of the 10th. This appears to be due to a turbulent solar wind, possibly assisted by small CME effects.

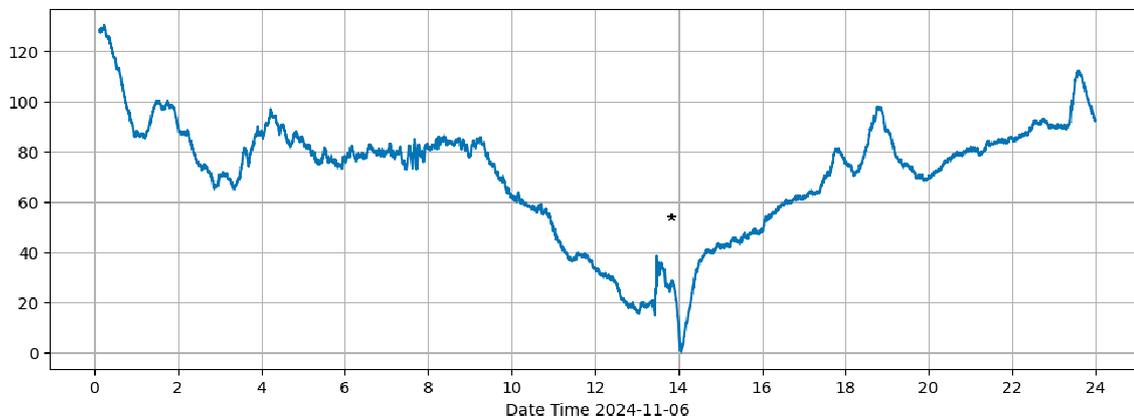

Roger Blackwell's chart shows the short active period from 18UT to 20UT, with a smaller disturbance earlier in the morning. Nick Quinn's recording also includes some activity on the previous day.

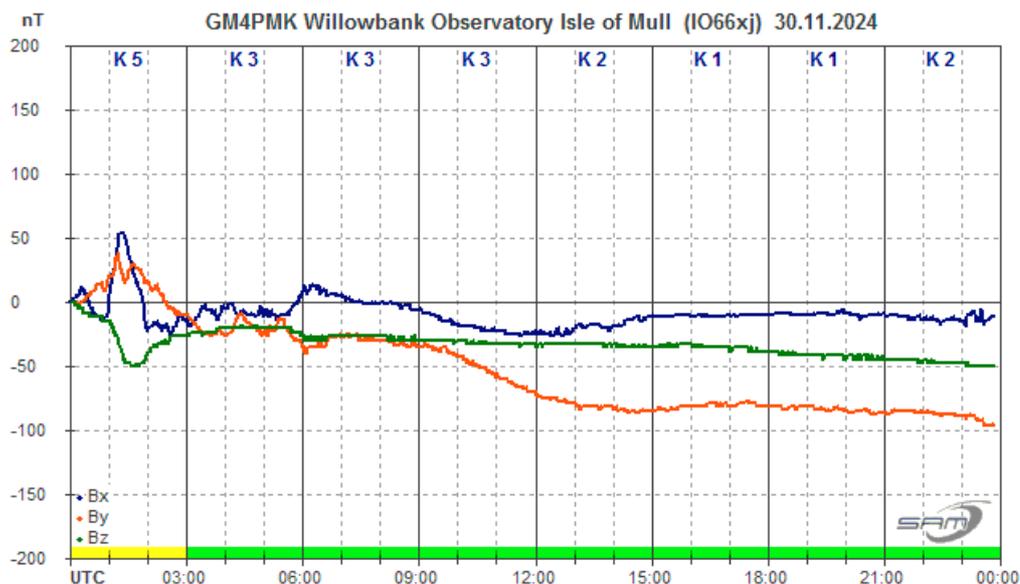

Steying Magnetometer (50.8 North, 0.3 West)

Wasbister Magnetometer (59.17N,3.06W)

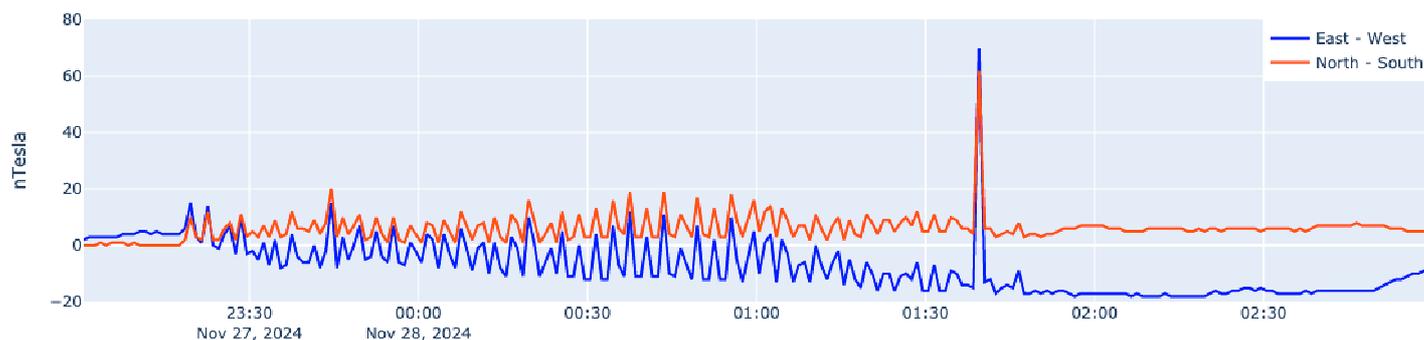

The X2.3 flare at 13:43 on the 6th has produced a Solar Flare Effect (SFE), where the sudden increase in ionisation of the D-region causes a strong electrical current to flow, thus rapidly altering the local magnetic field. Callum Potter has recorded this, marked '*' on his chart.

Magnetic disturbance remained very mild for the rest of the month, Roger Blackwell's recording from the 30th showing some weak effects from the solar wind.

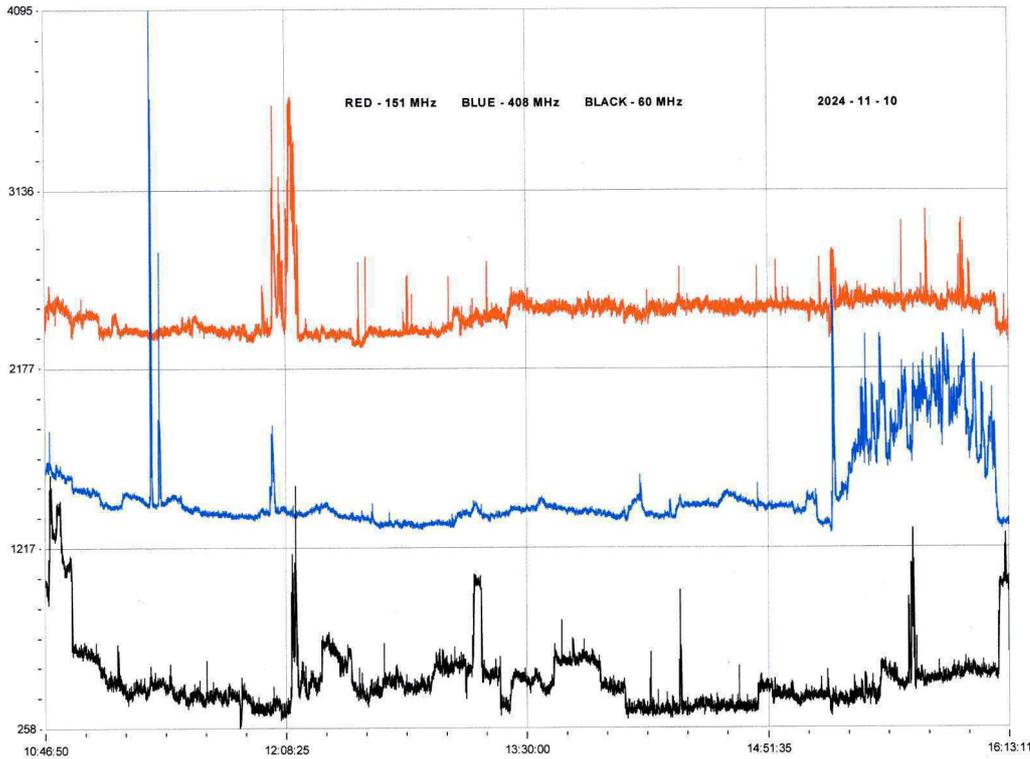

Steynning Magnetometer (50.8 North, 0.3 West)

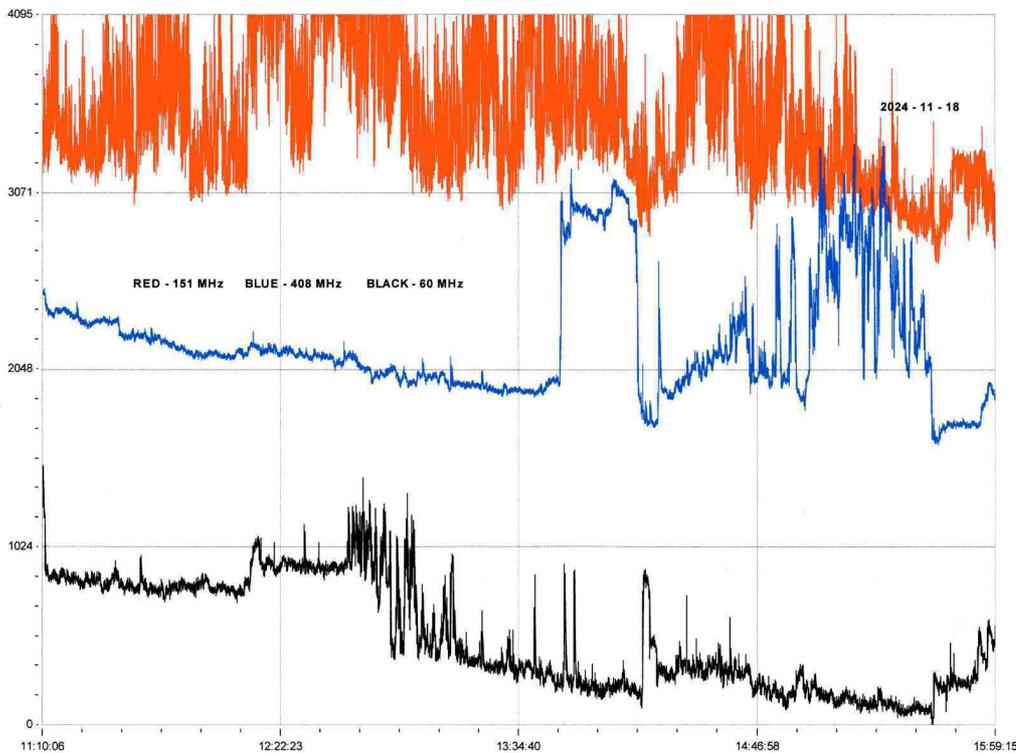

This recording from the 27th – 28th by Nick Quinn is rather a mystery. At first it looks very much like the example of PC2 waves shown in the October report, except that these waves have a period of about 3 minutes compared to 8 seconds for the PC2 waves. The sharp spike at the end of the cycle is also very different. None of our other observers have recorded anything similar, and so it must be some sort of local interference. The source however is unknown. A similar, but weaker, example was recorded on the 18th – 19th. Nick has eliminated household appliances as the cause by noting when they are used. All of the local interference that I have seen usually shows with sharp edges rather than a smooth cyclical pattern. I have seen the effects of local seismic disturbance of the sensor, but that would not be expected to last for over two hours. I have found references to minor seismic events in the north of England over this period, but nothing near the south coast. All suggestions welcome!

Magnetic observations received from Roger Blackwell, Callum Potter, Nick Quinn and John Cook.

SOLAR EMISSIONS

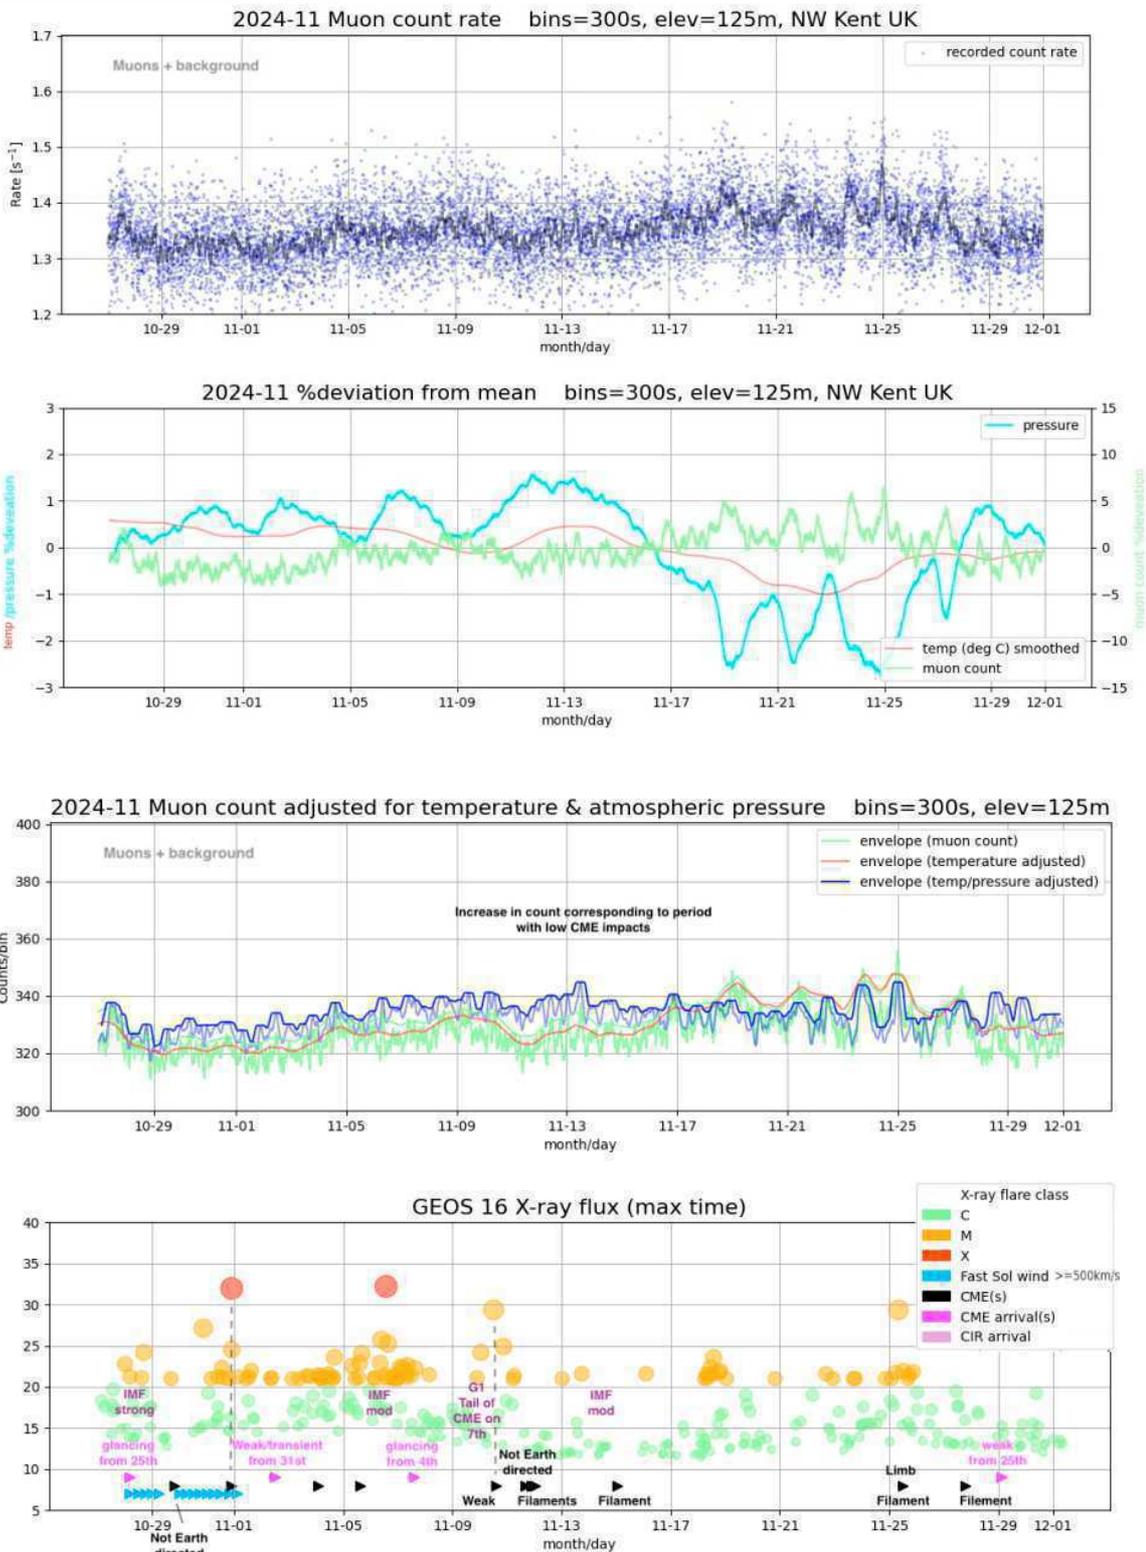

We recorded just a single SID on November 10th, from an M9.4 flare peaking at about 12:06–12:08UT. Colin Clements recorded a strong noise pulse on all three of his frequencies that match this flare very well. The 408MHz (blue) signal later in the day matches a smaller flare that we did not record as a SID.

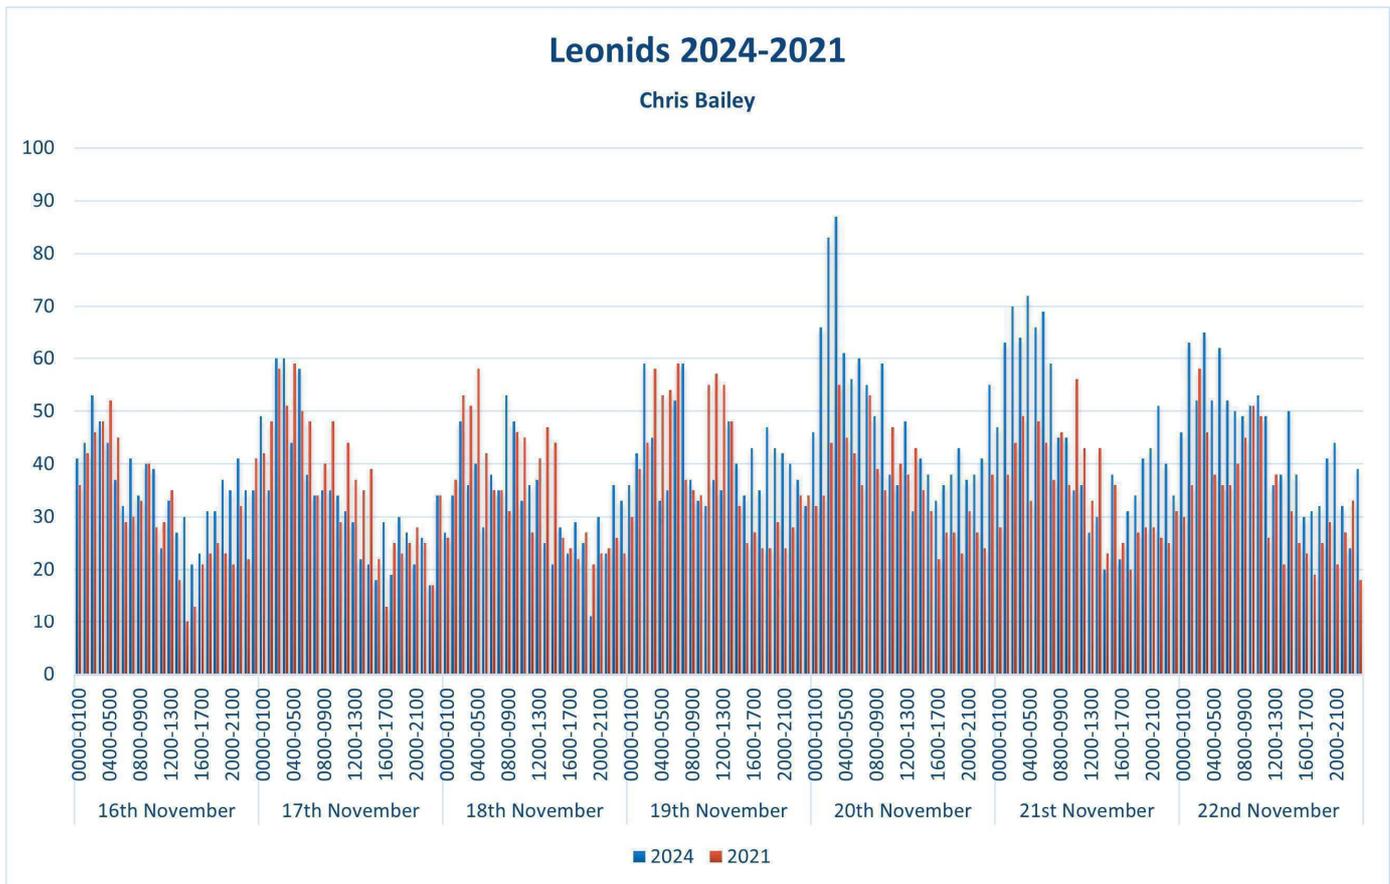

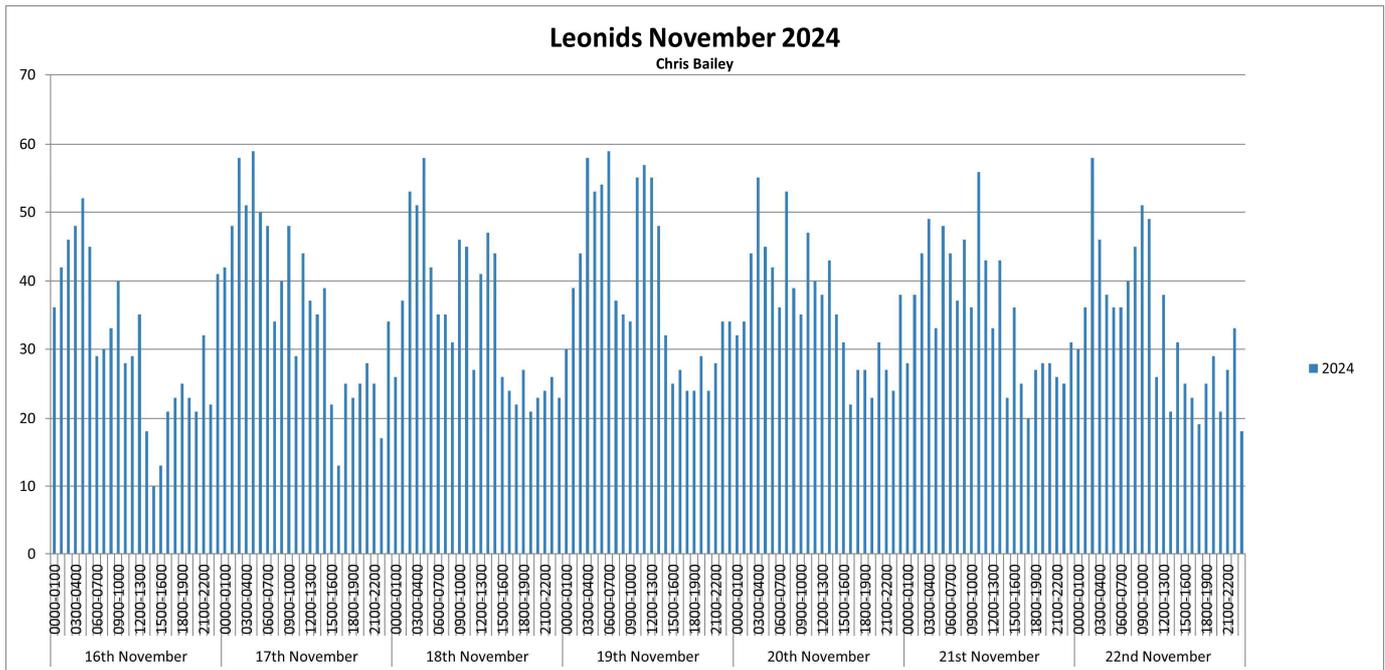

We recorded five M-class flares during the morning of the 18th, which may well have caused the 151MHz (red) noise in Colin's recording. 60MHz (black) has a shorter burst of noise that could be from the M3.7 flare, while 408MHz shows more noise later in the afternoon. A C4.3 flare later in the afternoon may well be related, although precise relationships are not clear. A very confusing pattern of activity.

MUONS

The Muon charts recorded by Mark Prescott show the dramatic drop in atmospheric pressure at the end of November as much as they show the Muon count. The raw data in the top chart shows the rise in Muon count with the low pressure, although the cause of the peaks on the 23rd and 24th is not clear. Higher solar activity earlier in the month has pushed up the counts, reaching a maximum by the 13th.

METEORS

Chris Bailey recorded the annual Leonid meteor shower, comparing it with his data from 2021. Counts seem to be fairly consistent from the 16th to 22nd, with a small peak on the 20th. Each day shows a peak early in the morning, as expected, with lower counts during the afternoon.
